To study the epidemiology of adult T-cell leukemia (ATL), cases of ATL were diagnosed in 23 Japanese cities from 1981 to 1983. This is a prospective epidemiological study with a standardized questionnaire and blood screening for human T-lymphotrophic virus-1 (HTLV-I) antibody. Initially, 118 cases of ATL were diagnosed and 875 controls were identified. Proportion of adult ATL cases was 2.4 times greater in the 15 to 44 years' age group than in the 45 to 64 years' age group. The male to female ratio of adult ATL was 3:1. The age-specific incidence rate of ATL in males was 9.7 and in females 4.9 per 100,000/year. Although the incidence rate of ATL increased with age in both sexes, the male-female ratio increased with age in the 45 to 64 years' age group. There was no difference in HTLV-I antibody status between the cases and controls. The study was inconclusive in regard to HTLV-I infection because the prevalence of HTLV-I antibody was low among the Japanese in 1981. Since we considered the sensitivity of ELISA, an examination of HTLV-I antibody status by Western blot was needed to reach the conclusion. The geographical pattern of ATL was different from that of HTLV-I antibody carriers. The pattern of distribution of adult ATL is considered to be different from that of HTLV-I carriers, and the relationship of HTLV-I carriers to adult ATL is discussed. is the nearest to 4/5?
