The metabolic changes in the animals after hemorrhagic shock (HS) were investigated. Male Wistar rats (200-250 g) were exposed to HS (mean arterial blood pressure (MAP) = 40 mmHg for 1 h), the ability of the animals to recover their blood pressure was examined with a 1 h shock period followed by a 1-h re-pressurisation period. The MAP was detected in 10 rats/group. Thirty rats were used for the experimental group, and 30 rats were used for the control group. The experimental group was given cysteamine 2, 3 or 4 mg/kg by intravenous injection while the control group was given an equal volume of normal saline. Fasting blood glucose (FBG) levels were significantly lower, while serum insulin levels were significantly higher in the rats given cysteamine (Cy) than those given the normal saline (NS). Cy increased the serum levels of immunoreactive glucagon (IRG) in the rats given 2 mg/kg and 4 mg/kg Cy compared with the NS-treated rats. The plasma levels of phosphor-insulin (PI) and free fatty acids (FFA) increased significantly in the rats given 2 mg/kg Cy but decreased significantly in the rats given
